Novel Interferometer-Spectrometer for Sensitive Doppler Planet Detection
David Erskine and Jian Ge

We describe a new compact and inexpensive instrument for detecting 1 m/s Doppler shifts of starlight (1/20,000th fringe shift) that can be extended to broad bandwidth, high efficiency and has 2 orders of magnitude greater étendue capability (for blurry sources) than the Lick Observatory spectrometer.

This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under contract No. W-7405-Eng-48.
